Physical vs. Controller Events

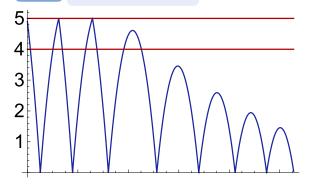

- Justifiable: Physical events (on ground x = 0)
- Justifiable: Physical evolution domains (above ground $x \ge 0$)
- Questionable: Controller evolution domain (x < 5)
- Unlike physics, controllers won't run *all* the time. Just fairly often.
- Ontrollers cannot sense and compute all the time.

If you expect the world to change for your controller's sake, you may be in for a surprise.

Delays vs. Events

- Periodically/frequently monitor for an event with a polling frequency / reaction time.
- Oelays may make the controller miss events.
- Oiscrepancy between event-triggered idea vs. real time-triggered implementation.
- Issues indicate poor event abstraction.
- Slow controllers monitoring small regions of a fast moving system.
- Ontroller needs to be aware of its own delay.

- Summary

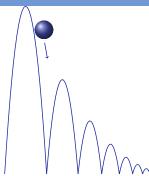

- Common paradigm for designing real controllers
- Periodical or pseudo-periodical control (iitter)
- Expects delays, expects inertia
- Implementation: discrete-time sensing
- Predict events, not just: if(eventnow(x)) ...
- Safe controllers know their own reaction delays
- Burden of event detection brought to attention of CPS programmer
- Time-triggered controls are implementable and more robust, but make design and verification more challenging!
- Use knowledge gained from verified event-triggered model as a basis for designing a time-triggered controller
